MAY 2002
A Hiring Subsidy for Long-Term Unemployed in a Search Model with PES and Random Search

Elke J. Jahn and Thomas Wagner

ABSTRACT: Our search model combines two search methods, the public employment service (PES) and random search. The separation rate is endogenous, the job matching process consists of three rounds. In the first and the second respectively the short-term (STU) and the long-term unemployed (LTU) randomly search for a vacancy. During the last round the PES matches registered job-seekers with registered vacancies. The LTU cause training costs and, during the training period, have a lower marginal product than the STU. The effects of the hiring subsidy and of profiling techniques to increase the effectiveness of the PES depend on the target group they are geared towards. For skill groups, who have relatively low private search costs in comparison with their productivity, not only the hiring subsidy but also the job placement activities of the PES are counterproductive and reduce overall employment.

KEY-WORDS: Matching model, hiring subsidy, endogenous separation rate, active labour market policy, PES, search market

Millard/Mortensen (1997), Mortensen/Pissarides (1999, 2001) and Pissarides (2000, ch. 9) are search models which analyse the effects of active labour market policies (ALMP) on equilibrium unemployment. In these models, the labour market is characterised by a matching technology which represents the two-sided search process with its frictions – due to imperfect information, mobility costs and heterogeneities. Each new match of a job seeker with a vacancy is entitled to a hiring subsidy. The hiring subsidy increases both the number of newly created jobs and the amount of job destruction. Therefore, its overall effect on equilibrium unemployment is ambiguous. Millard/Mortensen (1997) and Mortensen/Pissarides (1999, 2001) thus estimate the net effects of the subsidy with the help of numerical simulations.

Our model differs from the above-mentioned in the following respects. First, two search methods are available, the public employment service (PES) and random search (Pissarides 1979). Second, ALMP is available only for the long-term unemployed (LTU). A hiring subsidy is paid to firms which register their vacancy and fill it with a LTU worker placed by the PES. The PES also has the option to subsidise matches established through random search. Third, the model’s matching process consists of three subsequent phases. In the first and second phase respectively the short-term unemployed (STU) and the active job seekers among the LTU randomly search for a vacancy, in the third round the PES matches registered vacancies with the registered unemployed. Fourth, the unemployed choose between a passive and an active search strategy. The active LTU combine both methods of search. The passive unemployed wait for a placement through the PES.

The model generates the following results. (1) Equilibrium unemployment depends negatively on both unemployment incidence and duration, and on the fraction of passive job seekers. (2) Moreover, the hiring subsidy increases job destruction and unemployment duration of passive job seekers, and reduces the proportion of active job seekers among the STU and LTU as well as the job-to-job transitions. As a consequence, it decreases overall employment. (3) It increases the fraction of the LTU, their average outside wage, and the expenses of the PES for passive and active measures. (4) Furthermore, the LTU must accept a wage penalty. (5) Intuition - embodied for example in the German “Job-Aktiv-law” – recommends increasing the effectiveness of the public placement service in order to reduce equilibrium unemployment. This intuition is not confirmed by our model. (6) Strengthening the job seekers’ bargaining power decreases equilibrium unemployment.
This paper is structured as follows: In Section 2, the equilibrium rate of unemployment is derived. Section 3 introduces the asset equations of filled jobs and employed workers. Section 4 deals with job creation. Section 5 covers the asset equations of the unemployed and wage negotiations. In Section 6, the equilibrium values of the filled jobs, the dispersions of the outside wages of the LTU and the job destruction condition are derived. Section 7 presents a numerical simulation and section 8 provides a conclusion. The Appendix contains a graphical presentation of the simulation results.

2. STEADY STATE AND HIRING SUBSIDY

The time of the model is discrete\(^1\). Job creation takes place at the beginning, job destruction at the end of a period. The search process is two-sided. A continuum of vacancies searches for applicants, who can be of two different types: The first type are the short-term unemployed (STU) who have lost their job only at the end of the previous period. The second type are the long-term unemployed (LTU) who have been without a job for one period or more. The labour force is normalised to unity. Of the \(1 - u\) employed, \(\lambda G(R)(1 - u)\) lose their job at the end of the period. \(\lambda G(R)\) is the unemployment incidence where \(\lambda\) is the probability of an idiosyncratic productivity shock, \(G(x)\) with support \(0 \leq x \leq 1\) is the c.d.f. of the multiplicative shock \(x\) and \(R\) is the endogenous reservation productivity: \(yx \geq 0\), with \(y > 0\), is the flow output of a job. If a match draws productivity \(x\) with \(R \leq x \leq 1\), worker and firm decide to continue the job. If \(x < R\), the match terminates, the job becomes vacant, and the worker unemployed.

Methods and strategies of search. The model analyses the interactions of two search methods, the PES and random search. The search strategy of the vacancies is not specialised, that is, all vacancies are simultaneously posted on the private search market where they randomly search for a worker and are registered with the PES. Unemployed workers do not apply more than once per period and choose between an active and a passive search strategy.

Workers who lose their job register with the PES to claim unemployment benefit and to avail of the job placement service often only after days or weeks have passed. Once the PES is involved it reviews the right to the claim, registers and ad-

---

\(^1\) With respect to the differentiation between the STU and the LTU a model in discrete time is to be preferred to a model in continuous time. It is also easier to solve. The time period which best corresponds to the length of a model period is the yearly quarter. On the one hand the reference period should not be too short so as not to vary too much from the usual time limitations between the STU and the LTU (North America: 6 months and over, Europe: 12 months and over). On the other hand the reference period should not be too long because, as we assume, at least one model period elapses before the PES makes a first job offer to an unemployed worker.
vises the unemployed worker and finally refers him to the job placement service. The state placement agency then looks in the available data banks for match partners and makes a first job offer to the STU worker. When the addressee receives the offer at the end of the "reaction time" the STU worker has often already found a job. How much time passes between the beginning of an unemployment spell and the first job offer of the PES? Despite extensive research the authors of this paper have not found descriptive statistics on the distribution of the reaction time and have thus introduced the following assumption.

In the weeks or months before the first job offer of the PES the STU are certainly dependent on their own search efforts in the case that they decide on the active search strategy. We assume in the following that at least one period lies between the beginning of an unemployment spell and the first job offer of the PES in which there is definitely no job offer. Hence, the PES can place only the LTU. Moreover, the STU who have chosen the passive search strategy and leave the job search up to the PES can only assume a job offer from the PES in the following period at the earliest. The active LTU use both search methods (the PES and the private search market) simultaneously whereas only the method of random search is available to the STU.

Of the \( I \) workers who lose their job, \( S \) decide in favour of the active search strategy and immediately at the beginning of the next period start to search randomly for an unfilled vacancy. The other \( I - S \geq 0 \) workers prefer the passive strategy, and, with the beginning of the subsequent period, they belong to the group of LTU. The matching technology of the search market, which is specified below, generates the transition probability \( p \) that a given job seeker among the STU will find a vacancy. As the STU have a marginal product which is at least as high as that of the LTU and do not cause training costs, each match of a STU worker with an advertised vacancy results in an employment contract. Therefore, at the end of a period, the measure of the STU, \( u_S \), is

\[
I - pS = u_S. \tag{1}
\]

Search process. The search process consists of three phases, s. Fig. 1. In the first, only the \( S \) active job seekers among the STU are searching. They possess the best information about current labour market conditions and, therefore, their applications are more targeted and arrive earlier than the placements of the PES or the applications of the active job seekers among the LTU.

In the second round, advertised vacancies meet the \( S \) active job seekers among the LTU. Active job seekers among the LTU have the advantage that they can use both search methods simultaneously. Hence, in equilibrium their transition probability is higher than that of the LTU who have chosen to wait for a placement through
the PES. But using the search market generates search costs so that, in equilibrium, only a part of the unemployed decide on the active search strategy.

![Fig. 1: The search process](image)

In the last round of the matching process the PES arranges matches between registered vacancies and the registered unemployed.

**Transition probabilities.** Of the pool of unemployed, \( u - S \geq 0 \) workers choose the passive search strategy and wait for a placement via the PES. Their unemployment duration hazard i.e. their transition probability into employment is 
\[ P(1 - q_i)(1 - q_S)F(T_P), \]
where \( P \) denotes the probability of a contact with a vacancy found by the PES, \( q_i \) and \( q_S \) are the probabilities that the vacancy is already filled either by one of the \( S_i \) job seekers among the STU or by one of the \( S \) job seekers among the LTU. Each match with a LTU worker generates match specific training costs \( t \geq 0 \), of which ex ante only the c.d.f. \( F(t) \) and the reservation costs \( T_P \) are known. The reservation costs \( T_P \) are the training costs up to which firms and the LTU are interested in signing a job contract. A match with a LTU worker with training costs \( t > T_P \) is immediately dissolved again; the job remains vacant and the job seeker unemployed. Then, \( F(T_P) \) denotes the probability that the match partners face training costs \( t \leq T_P \), and, in a large economy, \( 1 - F(T_P) \) denotes the fraction of the LTU who cannot be placed via the PES.

The transition probability (or unemployment duration hazard) for the \( S \) active job seekers among the LTU is 
\[ (1 - q_i)\left[p_S F(T_S) + (1 - p_S)F(T_P)\right]. \]
First, the located vacancy must still be free. Second, the job seeker must draw training costs that are below the reservation costs of the respective search method. \( T_S \) is the reservation cost of the search market and \( T_P \) the reservation cost of the matching process organised by the PES. Third, even if random search is not successful, the active job seekers among the LTU still have the chance to be placed through the PES.

Summarising the flows into employment which result from the above transition probabilities and taking into account that \( u_S \) denotes the inflow into the pool of (long term) unemployed \( u \) yields the steady state condition:
\[ u_S = P(1 - q_i)(1 - q_S)F(T_P)u + p_S(1 - q_i)\left[F(T_S) - F(T_P)\right]S. \]
The LTU prefer the active search strategy only if the transition probability from combining the two methods of search is higher than that of the passive search strategy alone. This necessary condition for active job search is fulfilled iff \( F(T_S) > P(1 - q_S)F(T_P) \).

Unemployment duration. The duration of an unemployment spell depends on the search strategy chosen by an unemployed worker. If the worker leaves the job search up to the PES, then he will be unemployed for at least one period and the average length of time required for a job search will be:

\[
d_s = (1 - p_S)/(1 - q_S)\left[p_S F(T_S) + (1 - p_S)P(1 - q_S)F(T_P)\right].
\]

If the worker chooses the active search strategy then immediately after losing his old job he has the opportunity to look for a new one, which finds him acceptable, in the job advertisements. Because the probability of finding a job vacancy on the market is \( p_S \), the average duration of an unemployment spell is

\[
d_a = (1 - p_S)/(1 - q_S)\left[p_S q_S F(T_S) + (1 - p_S)P(1 - q_S)F(T_P)\right].
\]

If the two search strategies are compared in respect to the expected duration of the unemployment spell, then a job seeker who prefers the passive to the active strategy has to wait for at least one period longer to be matched with a new job which finds him acceptable, \( d_P > 1 + d_s \).

Matching function. The function \( m(x,v) \) represents the matching technology of the search market, where \( m \) is the number of contacts per period for a given measure of job seekers \( x \) and advertised vacancies \( v \). The matching function has constant returns to scale, is strictly concave and monotone in both arguments. Immediately at the beginning of a period, \( m(S, v) \) of the \( v \) advertised vacancies are filled by the STU who are actively searching. For a given vacancy posted at the beginning of the period, the probability of a match with a STU worker is

\[
q(\theta_1) = m(1/\theta_1,1) = m(S, v)/v,
\]

with \( \theta_1 = v/S \) denoting the tightness of the search market during the first round of the matching process. The transition probability of a given active job seeker among the STU is

\[ p(\theta_1) = q(\theta_1) \].

For convenience we write \( q_1 = q(\theta_1) \) and \( p_1 = p(\theta_1) \).

The \( S \) active job seekers in the unemployment pool \( u \) face the same \( v \) vacancies.

\[
m(S, v) \]

represents the measure of contacts, and \( q(\theta_2) = m(1/\theta_2,1) = m(S, v)/v \) is the contact probability of a given vacancy with one of the active job seekers among the LTU – with \( \theta_2 = v/S \) denoting the tightness of the search market during the second round of the matching process. The contact probability of a given job seeker is

\[
p(\theta_2) = q(\theta_2),
\]

and we write \( q_2 = q(\theta_2) \) and \( p_2 = p(\theta_2) \).

As all vacancies are advertised as well as registered, \( v \) is also an argument in the matching function \( M(u, v) \) of the PES, which has the same properties as \( m(x,v) \). \( M \) is the measure of contacts per period which the PES brings about with \( v \) registered vacancies and a stock of \( u \) registered (long-term) unemployed. For a given vacancy, therefore, \( Q(\theta) = M(1/\theta,1) = M(u,v)/v \) is the contact probability with a regis-
tered LTU worker via the PES – with \( \Theta = \nu/u \) denoting the tightness between both registers of the PES. Thus, for the registered unemployed, the probability of a contact with a registered vacancy is \( P(\Theta) = \Theta Q(\Theta) \).

Inserting equation (1) into equation (2), using \( l = \lambda G(R)(1-u) \) and taking into account the above definitions of the tightness in the three labour market segments, we obtain the following equation for equilibrium unemployment in the steady state

\[
u = \frac{\lambda G(R)}{\lambda G(R) + P(1-q_I)(1-q_S)F(T_p) + \Theta q_S (1-q_I)q_S [F(T_p) - P(t - q_S)F(T_p)]}.
\]

(3)

In a partial comparative static analysis, only the job destruction rate \( \lambda G \) and the reservation costs \( T_S \) have unambiguous effects with respect to the stock of unemployed (3). Unemployment increases with an increase in the separation rate and a decrease in the reservation costs.

**Hiring subsidy.** The PES is fully integrated (OECD 1996). First, it pays unemployment benefits to job seekers who have not found a job at the end of a period. Second, it matches registered vacancies with registered job seekers, and third it pursues active labour market policies (ALMP). In this last function, the PES pays a hiring subsidy to firms that enter into an employment contract with a LTU worker. The hiring subsidy is paid when the match partners sign the contract and incur the training costs \( t \geq 0 \). The hiring subsidy compensates, *de facto* or *de jure*, for the training costs which can be monitored by the PES without costs. Since the support of the distribution of training costs is not bounded from above, the PES defines a limit \( H \) on the hiring subsidy so that all matches with \( t \leq H \) receive a full repayment of \( t \), whereas matches with \( t - H > 0 \) have to finance the balance out of the match rent.

### 3. FILLED JOBS

Each match combines a vacant job with a job seeker. The partners of a new contact first determine the match specific training costs \( t \). If \( t \) exceeds the reservation costs, the agents separate immediately. Otherwise, they negotiate the conditions of the employment contract and start production thereafter.

An employment contract \([w_i, w(x) R]\) has three components. The first is the outside wage \( w_i \) which is paid to the worker throughout the initial period, the training period. It depends on his status \( i \) as a job seeker - on whether he is a STU worker with \( i = I \) or a LTU worker who has opted either for the passive, \( i = P \), or the active search strategy (which combines the two methods of search), \( i = S \). The second component of the contract are the match specific inside wages represented by the wage function \( w: [R, 1] \rightarrow \mathbb{R} \) that obtains after any productivity shock during the
continuation periods. After each shock to the match specific productivity, worker and firm renegotiate the conditions of the employment contract, especially the wage\(^2\). The third component defines the reservation threshold \( R \) at which the job will be destroyed.

**Continuation periods.** After the training period all jobs have the same productivity \( y \). Productivity shocks hit a match with probability \( \lambda \geq 0 \), are match specific, and manifest in the multiplicative productivity component \( x \), which is a random variable with c.d.f. \( G(x) \) defined on \( x \in [x,1] \). Within each period only one productivity shock can occur. Furthermore, the sequence of shocks are iid.

Let \( \Pi(x) \) be the present value of a filled job after the manifestation of a shock \( x \in [x,1] \). Worker and firm, considering their reservation utility, are both interested in continuing the match as long as \( \Pi(x) \geq 0 \) and agree on job destruction as soon as \( \Pi(x) < 0 \). Since \( \Pi(x) \) is a continuously monotonically increasing function of \( x \), as will be shown below, a reservation threshold \( R \) exists, for which

\[
\Pi(R) = 0. \tag{4}
\]

Only jobs with \( x \geq R \) will be continued. We assume that the firm markets the output \( yx \) at the end of the period at the same time as it pays the bargained wage \( xw \). Then the steady state equation for the present value \( \Pi(x) \) of a filled job is

\[
\Pi(x) = \rho \left[ yx - w(x) + \int_R^1 \Pi(h) dG(h) + (1-\lambda)\Pi(x) \right]. \tag{5}
\]

Flow and stock variables are discounted at the rate \( \rho \), where \( 0 < \rho = 1/1+r < 1 \) with the interest rate \( r > 0 \). With probability \( \lambda \) the job is hit by a productivity shock and changes into a state \( h \). If \( R \leq h \leq 1 \) the match is continued and the continuation asset value becomes \( \Pi(h) \). With probability \( 1-\lambda \) the match specific productivity does not change.

A worker who is employed at the match specific productivity \( yx \) gets the wage \( w(x) \), and his human capital has the present value \( W(x) \). The asset pricing equation for \( W(x) \) is

\[
W(x) = \rho \left[ w(x) + \int_R^1 W(h) dG(h) + G(R)w(x) + (1-\lambda)W(x) \right]. \tag{6}
\]

With probability \( \lambda \) a shock occurs and the match draws the productivity \( h \). If \( h \geq R \), the value of the worker is \( W(h) \) and the match continues. If, on the other

\(^2\) Mortensen/Pissarides (1999) and Pissarides (2000) present a discussion of objections against the plausibility of this assumption and the two-tier wage structure which results from the possibility of renegotiation.
hand, \( h < R \), which occurs with probability \( G(R) \), the job is destroyed, the worker becomes short-term unemployed and the value of his human capital is \( U_i \).

**Training period.** Firms choose the initial productivity when they set up the match and negotiate the outside wage. If the job seeker is a STU worker, the initial productivity is set at \( x = 1 \). Moreover, the STU do not generate training costs and therefore the initial value \( \Pi_i \) of a job filled by a STU worker is

\[
\Pi_i = \rho \left( y - w_i + \lambda \int_{R}^{1} \Pi(h) dG(h) + (1 - \lambda) \Pi(t) \right),
\]

with \( w_i \) denoting the negotiated wage. If the match is not hit by a shock, the worker’s productivity remains at \( x = 1 \) in the continuation period as well, and the filled job has the value \( \Pi(t) \). The human capital of a worker who starts production as a STU worker is

\[
W_i = \rho \left( w_i + \lambda \int_{R}^{1} W(h) dG(h) + G(R) U_i + (1 - \lambda) W(t) \right),
\]

where \( W(t) \) denotes the value of the worker in the continuation period if no productivity shock occurs.

The LTU find a vacancy either through random search or via the PES. When wage negotiations between a vacancy and a LTU worker start, jobs filled by the STU are already productive. Moreover, the LTU need a training period and, therefore, their initial productivity \( yz \) is lower than the productivity of a STU worker, \( z \leq 1 \). The allocation of the training costs and the hiring subsidy is subject to negotiation, but the outside wage \( w_i(t) \) and the initial value of the job \( \Pi_i(t) \) depend only on \( t \) if \( t \) exceeds the subsidy limit \( H \). For the sake of brevity, we present the asset equations only for the case \( t - \tau > 0 \), where the indicator variable \( \tau \) takes the value of one if \( \tau = 1 \). For a job which is filled with an active job seeker among the LTU \( i = S \) and \( \tau = 1 \), with \( \tau = 0 \) if the PES also subsidises the matches via the search market, otherwise \( \tau = 0 \). Considering the status of the job seeker \( i = P, S \), the present value of a job filled with an LTU worker is given by

\[
\Pi_i(t) = \rho \left( yz - w_i(t) + \lambda \int_{R}^{1} \Pi(h) dG(h) + (1 - \lambda) \Pi(t) \right), \text{ for } \tau \leq t \leq \tau_j.
\]

Taking into account the negotiated outside wage \( w_i(t) \), the present value of the worker’s human capital during the training period is

\[
W_i(t) = \rho \left( w_i(t) + \lambda \int_{R}^{1} W(h) dG(h) + G(R) U_i + (1 - \lambda) W(t) \right), \text{ for } \tau \leq t \leq \tau_j.
\]
4. JOB CREATION AND RESERVATION COSTS

All vacancies are advertised and registered, no vacancy specialises in one of the two search methods\(^3\). Entrance into the labour market is free for all vacancies, but open only at the beginning of a period. The flow of vacancies therefore persists until the present value of a vacancy is driven to zero, \( V = 0 \). Considering this infinitely elastic supply of vacancies, the *job creation* condition is

\[
0 = -k + q_I \Pi_I + (1 - q_I)V_I,
\]

where \( k \) denotes the flow costs for advertising and for registration with the PES. If there is no contact with a STU worker in the first round of the matching process - an event which has the probability \( 1 - q_I \) - the vacancy takes on the value \( V_I > 0 \).

There are three reasons for the existence of the outside option \( V_I \). First, vacancies are not specialised. Second, the matching process consists of three rounds. A vacancy that is not filled during the first has the option to meet a LTU worker who is actively searching for a job or placed by the PES in the second or third round of the matching process respectively. The value of this option is \( V_I \). Third, the supply of vacancies is perfectly inelastic in the last two rounds of the matching process.

The above *job creation* condition can also be interpreted as follows. Due to search costs, each successful match generates a positive rent, which is distributed between worker and firm through the wage. \( \Pi_I - V_I \) is the firm’s share of the rent of a match with a STU worker, \( \Pi_I \) is the value of the filled job, and \( V_I \) is the value of the outside option of the vacancy. The price which the firm pays for participating in the matching process is \( k \), the *implicit* price for the first round is \( k - V_I \). Thus, the *job creation* condition states that the flow of vacancies into the labour market lasts until the implicit search cost a firm has to incur to take part in the first round of the matching process equals its share of the match rent:

\[
\frac{k - V_I}{q_I} = \Pi_I - V_I. \tag{11}
\]

The option value \( V_I \) of a vacancy at the end of the first round of the matching process, when the search costs \( k \) are sunk, is

\[
V_I = q_S V_S + \left[1 - q_S F(T_S)\right] Q V_F, \tag{12}
\]

where \( q_S \) denotes the probability that the vacancy will be filled by a LTU worker who is actively seeking, \( V_S \) is the conditional expected value of a job which has contact with such a worker. If the vacancy does not meet such a worker or if the

---

\(^3\) Specialisation may occur due to the heterogeneity of the job seekers or the jobs or because of increasing search costs. We assume that the search cost function of a vacancy with respect to the two search methods is sub-additive, so that, considering the asset value of a vacancy, it is advantageous for firms to offer vacancies through both channels.
training costs of the applicant exceed $T_S$ — a composite event with the probability $1 - q_S F(T_S)$ — then the vacancy still has the third option to meet a LTU worker placed by the PES. The probability of a match with a LTU worker placed by the PES is $Q$, and the conditional option value of the job is $V_P$.

**Reservation costs.** The hiring subsidy of the PES compensates for the training costs up to the limit $H$. Matches with the LTU placed by the PES and with training costs $t$ higher than $H$ must finance the balance $t - H \geq 0$ out of the match rent. The allocation of the balance is part of the contract negotiations, and the value of the filled job, $\Pi_P(t)$, therefore depends on $t$. As will be shown, $\Pi_P(t)$ is a monotonically increasing function of $t$, while the net value of the job, $\Pi_P(t) + H - t$, is a contraction and fulfills the reservation property with respect to $t$. Hence, reservation costs $T_P$ exist, with

$$T_P = \Pi_P(T_P) + H.$$  \hspace{1cm} (13)

Match partners whose training costs are lower than $T_P$ sign an employment contract while match partners with $t > T_P$ separate immediately.

A vacancy filled by a LTU worker who is actively searching has the value $\Pi_S(t)$ if the match draws training costs $t$, with $t - H \geq 0$. In view of the third round of the matching process, $QV_P$ is the outside option of the firm. Therefore, the job will only be filled if its net value is at least as high as the value of the option to meet a LTU worker placed by the PES, $\Pi_S(t) + H - t \geq QV_P$. Since the net value of the job has the reservation property, reservation costs $T_S$ also exist for the method of random search

$$T_S = \Pi_S(T_S) + H - QV_P.$$  \hspace{1cm} (14)

5. **The Value of Unemployment and Wage Negotiations**

A worker who has lost his job must decide between the active and the passive search strategy. The worker chooses the strategy which maximises the present value of his human capital $I_U$

$$U_I = \max \left\{ p(b + U) - c_I + p_I W_I + (1 - p_I) p(b + U) \right\},$$  \hspace{1cm} (15)

where $b = b_U + b_I$ is the gross unemployment benefit. The choice set of the Bellman equation (15) contains two alternatives. First, if the worker prefers the passive strategy, he receives the exogeneous unemployment benefit $b_U$ at the end of

---

*Appendix AI contains the asset pricing equations for $V_S$ and $V_P$. *
the period and enjoys utility of leisure $b_1$, while his human capital takes on the value $U$. In the subsequent period he has to decide again whether to wait for a placement via the PES or to search and apply for a vacancy on the market. In the first case, the value of his human capital is $U_P$, in the second, it is $U_S$. The worker will opt for the search strategy that maximises the present value of his human capital so that

$$U = \max \{U_P, U_S\}. \tag{16}$$

Second, if the STU worker chooses to search randomly, he incurs search costs $c_s > 0$. With probability $p_s$, he will locate a vacancy, and the value of his human capital is $W_S$. With probability $1 - p_s$ his search will be in vain, he receives the gross unemployment benefit $b$, and his human capital takes on the value $U$.

The present value of the human capital of a LTU worker who waits for a placement via the PES is

$$U_P = P\left( (1 - q_1)(1 - q_s) \int_0^\rho W_P(t) dF(t) + \left[ 1 - F(T_P) \right] \rho (b + U) \right) + \left[ q_1 + (1 - q_1)q_s \right] \rho (b + U) + (1 - P) \rho (b + U), \tag{17}$$

If the LTU worker is matched and if the vacancy for which he applies is not yet filled – the probability for this composite event is $P(1 - q_1)(1 - q_s)$ – the value of his human capital is $W_P$ provided that the subsidy compensates fully for his training costs, that is if $t - H \leq 0$. Otherwise, if his training costs exceed $H$ but are lower than the reservation costs $T_P$, the integral in (17) denotes the expected value of the employed human capital. If the training costs exceed $T_P$, vacancy and applicant separate, and the present value of the worker is $\rho (b + U)$ as in the cases where the vacancy is already filled or the LTU is not offered a vacancy by the PES.

If the LTU worker decides on the active search strategy, he will incur search costs $c_S > 0$. Considering the contact probability $p_S$ generated by the search market, the value of his human capital is $U_S$ with

$$U_S = -c_S + p_s \left\{ (1 - q_1) \left[ F_s(H)W_S + \int_0^\rho W_S(t) dF(t) + \left[ 1 - F(T_S) \right] U_P \right] + q_1 U_P \right\} + (1 - p_s) U_P. \tag{18}$$

If the job search fails – either because the LTU worker is confronted with a vacancy already filled or because he incurs training costs that exceed $T_S$ or because $\text{For simplicity we assume that } b_1 \text{ is exogenous. The endogenisation of } b_1 \text{ (Mortensen / Pissarides 2001) lowers the incentive to search and thus strengthens the comparative static effects of } H, \text{ which are shown in Section 7.}$
he does not find a vacancy – his human capital takes on the value of the passive
strategy $U_P$ because placement via the PES is the final option which concludes the
matching process.

**Wage negotiations.** Job search takes time and causes search costs. Therefore,
each match generates a positive monopoly rent which is distributed between the
match partners through the wage. The distribution rules are obtained according to
the generalised Nash solution to a bargaining problem, with $\beta \in (0,1)$ denoting the
bargaining strength of the job seeker.

If a STU worker meets a vacancy, the outside wage $w_i$ for the initial period of the
match is derived from the sharing rule

$$W_i - U_i = \frac{\beta}{1 - \beta} (\Pi_i - V_i),$$

with $V_i$ denoting the reservation value of the vacancy, which follows from the
firm’s option to fill the vacant job with a LTU worker during the subsequent rounds
of the matching process.

If the vacancy meets a LTU worker, the sharing rule depends on the design of
ALMP, whether the PES compensates fully for the training costs, or whether the
agents have to negotiate the allocation of the balance $t - \tau H \geq 0$. For the sake of
brevity, we present the sharing rules for the case $t - \tau H \geq 0$. For wage negotiations
with a LTU worker who is randomly searching the sharing rule is

$$W_S(t) - U_S = \frac{\beta}{1 - \beta} \left[ (\Pi_S(t) + t H - t) - QV_P \right], \text{ for } t H \leq \tau,$$

where $W_S(t) - U_S$ is the job seeker’s share of the rent, and $QV_P$ is the expected
reservation value of the vacancy given the third round of the matching process. For
wage negotiations with a LTU worker placed by the PES the following sharing rule
is implemented:

$$W_P(t) - U_P = \frac{\beta}{1 - \beta} \left[ (\Pi_P(t) + H - t) \right], \text{ for } H \leq t \leq T_P,$$

where $\Pi_P(t) + H - t$ is the firm’s share of the rent. Taking into account the idio-
syncratic productivity shock $x \in [R,1]$, the value of a STU worker, $U_i$, and the fact
that in equilibrium the asset price of a vacancy is $V = 0$, the sharing rule used for
the negotiations with an insider is

$$W(x) - U_i = \frac{\beta}{1 - \beta} \Pi(x).$$
Considering the asset pricing equations (5) – (10) and the sharing rules (19) – (22), we obtain

**Lemma 1 [Bargained Wages].** Given the reservation income \( rU_I \) of a STU worker and the asset values \( U_S \) and \( U_P \) of the LTU who prefer the active or the passive search strategy respectively, the agents negotiate the following inside and outside wages.

(i) The bargained inside wage at a match specific productivity \( x \in [R, 1] \) is

\[
    w(x) = rU_I + \beta(yx - rU_I).
\]  

(ii) A STU worker who makes a job-to-job transition and produces, in the initial period, with productivity \( x = 1 \) receives the outside wage

\[
    w_I = w(1) - \beta r I V p^{-1},
\]  

where \( w(1) \) is the inside wage (23) for \( x = 1 \), and \( p^{-1} = 1 + r \).

(iii) If the PES subsidises the training costs, a LTU worker with human capital \( U_P \) placed by the PES receives the outside wage \( w_P \) with

\[
    w_P = w(t) - \beta (1 - z)y + (1 - \beta)(U_P - U_I)p^{-1}, \text{ for } t \leq H.
\]  

where \( yz \), with \( z \leq 1 \), is the flow output in the training period.

If \( H \leq t \leq T_P \), the outside wage \( w_P(t) \) in the training period is

\[
    w_P(t) = w_P - \beta (t - H)p^{-1}.
\]  

(iv) A LTU worker with human capital \( U_S \) who finds a job through random search receives the outside wage \( w_S \) if the PES subsidises his training costs:

\[
    w_S = w(t) - \beta (1 - z)y + (1 - \beta)(U_S - U_I)p^{-1} - \beta Q V P p^{-1}, \text{ for } t \leq tH.
\]  

If the training costs exceed \( tH \), the bargained wage is

\[
    w_S(t) = w_S - \beta (t - tH)p^{-1}, \text{ for } tH \leq t \leq T_S.
\]  

As equation (23) shows, the inside wage equals the reservation income of the worker plus a share of the current match rent that depends on his bargaining strength \( \beta \). As (19) shows, the value of the outside option \( V_I \) diminishes the rent of a match with a STU worker, and, as a consequence, reduces the share of the current rent (24) a STU worker can appropriate in the contract negotiation. The time of the model is discrete. While the reservation value of the vacancy refers to the beginning of the period, wages are paid at the end; \( V_I \), therefore, is discounted in (24)
to the end of the period. The lower the productivity $z \leq 1$ of a LTU worker during the training period, the lower the bargained outside wages, as equations (25) and (27) show. Moreover, training costs higher than $H$ are partially passed on to the worker, so that the outside wages (26) and (28) respectively fall monotonically with $t$. Finally, the outside wage of a LTU worker depends on the sign and the magnitude of the balance of the present values of a LTU and a STU worker, $U_P - U_I$, as the wage equations (25) and (27) show.

Two factors influence the differential rent $U_P - U_I$. First, the employment service of the state agency is only available to the LTU, while the STU in view of the reaction time of the PES either have to wait until the next period if they choose the passive search strategy, or to search by themselves. Therefore, the sign of the balance also depends on the search strategy the STU prefer.

If $U_I > \rho(b + U)$, then all STU workers immediately search for a new job. The number of active job seekers $S_I$ among the STU rises, the tightness $\theta_I$ of the search market in the first round of the matching process diminishes, and the transition rate $p_t$ falls. The adjustment comes to an end either because the gains from private job search are driven to zero, as $U_I = \rho(b + U)$, or because the total inflow searches randomly for a job, so that $S_I = I$. In the following, we look at the first case and assume that in equilibrium the gains from search vanish so that $U_I = \rho(b + U)$ and $S_I \leq I$.

If in equilibrium the STU are indifferent to the active and the passive search strategy, then, the differential rent $U_P - U_I$ is strictly positive and can be derived from the asset equation (17), the sharing rule (21), and equation (A1) for the option value $V_P$ of a vacancy that, in view of the third round of the matching process, expects to meet a LTU worker placed by the PES:

$$U_P - U_I = \frac{\beta}{1 - \beta} \frac{P(1 - q_I)(1 - q_S)W_P}{1 - P(1 - q_I)(1 - q_S)F(T_P)}.$$ (29)

If the STU are indifferent to both search strategies then the differential rent (29) is strictly positive. The reason for this is the reaction time of the PES: the PES is available to the LTU whereas it is not to the STU who have just lost their jobs; the STU must wait at least one period - after the PES has reviewed their claims, has registered and referred them to the job placement service - until the first job offer arrives. During this time, which we assume lasts one period, the STU have to rely on their own search efforts. The differential rent (29) increases together with the probability $P$ for a contact via the PES, the reservation costs $T_P$, the probability $(1 - q_I)(1 - q_S)$ of finding a job that is not yet filled by one of the active job seekers, and with the option value $V_P$. 
The LTU choose the active search strategy if $U_S > U_P$. The number of active job seekers $S$ increases, the tightness $\theta_S$ of the search market during the second round of the matching process decreases, and the contact probability $p_S$ diminishes until either all workers in the unemployment pool $u$ search actively for a job, so that $S = u$, or the gains from private job search vanish, so that $U_S = U_P$ and $S \leq u$. In the following, we investigate the second case and assume that, in equilibrium, $U_S = U_P$ and $S \leq u$. With $U_S = U_P$, the LTU are indifferent to the strategies of search, and from the wage equations (25) and (27) it follows for the outside wage of a random searcher among the LTU: $w_S = w_P - \beta Q V P^{-1}$, for $t \leq H$.

6. The Value of a Filled Job, Wage Dispersions and Job Destruction

With the wage equations from Lemma 1, the asset equations from section 3, and the condition of the reservation productivity (4), we can now derive the value of a filled job.

**Lemma 2 [Filled Jobs].** (i) After the training period the continuation value of a filled job producing with the idiosyncratic productivity $x \in [R,1]$ is

$$\Pi(x) = (1-\beta)^y \frac{x - R}{x + R}.$$  \hspace{1cm} (30)

(ii) Taking into account the reservation value $V_i$, a job filled by a STU worker has the present value

$$\Pi_i = \Pi(t) + \beta V_i,$$  \hspace{1cm} (31)

where $\Pi(t)$ is the continuation value (30) for the match productivity $x = 1$.

(iii) A job filled by a LTU worker who is placed and whose training costs are subsidised by the PES has the value

$$\Pi_P = \Pi(t) - \rho((1-\beta)(1-y) - (1-\beta)(U_P - U_i)),$$  \hspace{1cm} (32)

for $H_t \leq H$.

A job filled by a subsidised LTU worker whose training costs exceed $H$ has the present value

$$(\Pi_P(t) = \Pi_P + \beta (t - H),$$  \hspace{1cm} (33)

for $H \leq t \leq T_P$.

(iv) Since the job seekers are indifferent to the two search strategies, taking into account the reservation value $Q V_P$, a job filled by a LTU worker who is actively searching has the asset price

$$\Pi_S = \Pi_P + \beta Q V_P,$$  \hspace{1cm} (34)

for $t \leq H$.

For training costs $t$ with $H \leq t \leq T_S$ we finally obtain
\[ \Pi_S(t) = \Pi_S + \beta(t - 1H). \] (35)

From the value equations for the filled jobs, we can derive the reservation costs \( T_P \) and \( T_S \).

**Lemma 3 [Reservation Costs].** (i) The reservation costs \( T_P \) which are applied to the LTU who are placed by the PES follow from (33) together with \( \Pi_P(T_P) + H - T_P = 0 \):

\[ T_P = \frac{\Pi_P}{1 - \beta} + H. \] (36)

From the value equations (33) - (35) and \( T_S = \Pi_S(T_S) + H - QV_P \) we can derive the reservation costs for the method of random search

\[ T_S = T_P - (1 - \iota)H - QV_P. \] (37)

(ii) As a consequence of the fact that \( T_P - T_S = (1 - \iota)H + QV_P > 0 \), the percentage of LTU who cannot be placed via the search market, is always higher than the percentage of LTU who cannot be placed via the PES: \( 1 - F(T_S) > 1 - F(T_P) \).^6

The dispersions of the outside wages of the LTU during the training period depend on the method of search and the distribution of the training costs.

**Lemma 4 [Wage Dispersions].** (i) The dispersions of the outside wages of the LTU are defined on the ranges \((w_P(T_P), w_P)\) and \((w_S(T_S), w_S)\), where \( w_i(T_i) \) is the lowest and \( w_i \) is the highest wage of the respective wage dispersion, \( i = P, S \). From Lemma 1 and Lemma 3, taking into account that in equilibrium \( U_S = U_P \), it follows that \( w_P(T_P) = w_S(T_S) \) and \( w_P - w_S = \beta QV_P \).

(ii) The average wages of the normalized dispersions are given by \( \bar{W}_P = \frac{F(\Phi)w_P + \int_{\Phi}^{T_P} w_P(t)dF(t)}{F(T_P)} \) and \( \bar{W}_S = \frac{F(\Phi)w_S + \int_{\Phi}^{T_S} w_S(t)dF(t)}{F(T_S)} \).

If the training costs are exponentially distributed, then \( \bar{W}_P > \bar{W}_S \).

The job destruction rule can be derived by evaluating the asset equation (5) at the reservation threshold \( x = R \). Taking into account the wage equation (23) we obtain:

\[ 0 = R - \frac{\lambda U_1}{Y} + \frac{\lambda}{\lambda + \rho} \int_{R}^{\lambda}(h - R)dG(h). \] (38)

^6 With Lemma 2 and Lemma 3 the option values of a vacancy \( V_P \) and \( V_S \) are only functions of the subsidy limit \( \Pi \), the reservation costs \( T_P \) and \( T_S \), the tightness \( \Theta \), and the design \( \tau \in [0,1] \) of the ALMP (s. App. A).
In order to close the model, we still have to determine the reservation income of a STU worker, \( rU_I \), and the transition probabilities of the method of random search.

In equilibrium the STU and the LTU, by assumption, are indifferent to the active and the passive search strategies so that \( U_I = \rho(b + U) \) and \( U_P = U_S = U \). With these assumptions, the reservation income of a STU worker is equal to the sum of the unemployment benefit and the increment in the value of his human capital at the point of transition to the state of the LTU:

\[
rU_I = b + (U_P - U_I). \tag{39}
\]

Taking account of the fact that job seekers are indifferent to the two search strategies, we finally obtain the transition probabilities generated by the search market, \( \rho(\theta_I) \) and \( \rho(\theta_S) \), as follows.

**Lemma 5 [Random Search].** (i) From the Bellman equation (15) and \( U_I = \rho(b + U) \) it follows that, in equilibrium, the expected search costs of a STU worker who is randomly searching are equal to his share of the match rent, \( c_I / \rho_I = W_I - U_I \). From this, together with the sharing rule (19) and the asset equation (31), we obtain

\[
\frac{c_I}{\rho_I} = \frac{\beta}{1-\beta} \left[ \Pi(t) - (1-\beta)W_I \right]. \tag{40}
\]

(ii) Using the assumption \( U_P = U_S = U \) and the asset equation (18), it follows that, in equilibrium, the expected search costs of a LTU worker who is randomly searching equal his expected share in the match rent:

\[
\frac{c_S}{\rho_S} = \frac{\beta}{1-\beta} \left[ \Pi(t) - (1-\beta)W_S \right]. \tag{41}
\]

The equilibrium of the search model consists of solutions \( \{U_I, U_P, \theta_I, \theta_S, R, T_P, T_S, u\} \) to the equations (A5) – (A12) in Appendix II and the equilibrium unemployment (3). The comparative static effects of the hiring subsidy are indeterminate as a consequence of the multiplicity of the channels through which ALMP work. Which effect dominates is an empirical question. We therefore have carried out a series of numerical experiments.
7. SIMULATION

Parameters and matching functions. The choice of the baseline parameter values, Table A1 in Appendix II, is made with respect to the design of the experiments of Mortensen/Pissarides (1999, 2001) and the restraint that in equilibrium the number of active job seekers, $S_l$ and $S$, have to be “interior solutions” to the model.

The time period which corresponds to the duration of a model period is the yearly quarter. The bargaining power of the workers is $\beta = 0.50$; the marginal product of a job at full productivity is $y = 100$. During their training period, the LTU produce a marginal product of $yz = 60$; the value of leisure is $b_l = 30$, UI benefits are $b_J = 30$, so that $b = b_l + b_J = 60$; the real interest rate $r$ is 2%; the probability of a productivity shock is 10%; the search costs are $c_I = 40$ and $c_S = 25$, and the recruiting costs of a vacancy amount to $k = 30$.

The distribution function $G(x)$ of the productivity shocks is assumed to be uniform on $[\alpha, 1]$, with the lower support $\alpha = 0.65$. Training costs $t \geq 0$ are exponentially distributed with mean $1/\delta = 15$.

The matching functions of the PES and the search market are of the Cobb-Douglas type (Petrongolo/Pissarides 2001). For a given vacancy the probabilities of a contact with a job seeker are

\begin{align*}
\text{PES:} & \quad Q(\theta) = ef \times (1/\theta)^{1-\phi} \quad (42) \\
\text{Search market:} & \quad q(\theta) = d \times (1/\theta)^{1-\phi}. \quad (43)
\end{align*}

The values of the "total factor productivities" of the basic scenario are $ef = d = 0.30$; for the elasticities of the job matches $M$ and $m$ with respect to vacancies we use $\Phi = 4/5$ and $\phi = 1/5$ respectively. Thus, among the arguments of the matching technology of the PES, the vacancies dominate, while on the search market the active job seekers are the dominating input factor.

Indicators. The following indicators are used to evaluate the simulations: (1) Quarterly unemployment rate $U$ in percent; (2) quarterly unemployment incidence $\lambda$ in percent; (3) unemployment duration of active and passive job seekers $d_a$ and $d_p$ respectively in quarters; (4) fraction of active job seekers among the inflowing STU, $S_l/I \times 100$; (5) fraction of active job seekers among the LTU, $S/I \times 100$; (6) fraction of the STU making job-to-job transitions, $p_I S_l/I \times 100$; (7) the outside wage $w_I$ negotiated by the STU making job-to-job transitions; (8) the indicator for the outside wages of the LTU, which equals the mean of the distribution of outside wages, s. Lemma 4, as a percentage of the outside wage of the STU, $w_IP = w_P/\bar{w}_I \times 100$. $100 - w_IP$ denotes the average wage penalty which a LTU worker placed through the PES must accept due to his low productivity and the
training costs. (9) fraction of the LTU, $LTU = (1 - u_2/u) \times 100$; (10) market share of the PES, $PES$ (see App. II for a definition); (11) UI benefits as a percentage of the net product, $PLMP = u_{b_u}/np \times 100$. The net product is $np = (1-u)\int_{R}^{1} x dG(x) / [G(1) - G(R)]$, where the term $(1-u)y$, which denotes the net product for $x = 1$, is weighted with the conditional expected value of the productivity parameter $x \geq R$. (12) Expenses of the PES for active labour market policies in percent of the net product, $ALMP$ (s. App. II).

The results of the simulation with the limit $H$ on the hiring subsidy are shown graphically in the Appendices III – V. We distinguish between an ALMP design which supports only placements through the PES (regime $\iota = 0$) and a policy which gives equal support to both search methods (regime $\iota = 1$). Appendix III shows the results for both regimes ($\iota = 0$ and $\iota = 1$) with the baseline parameter values from Tab. A1. Appendix IV describes the results for $\iota = 0$ at different values for the workers’ bargaining strength ($\beta = 0.45$ and $\beta = 0.55$). Appendix V depicts the results for $\iota = 0$ at varying values for the matching productivity of the PES ($ef = 0.25$ and $ef = 0.35$). The App. IV und V show clearly that the results 1 – 4 are also stable with shocks which affect central model parameters. Moreover, App. IV und V show additional results which are based on the effects of the policy parameter $ef$ and the structural parameter of the wage bargaining system $\beta$.

**Result 1.** The three figures, App. III – V, show that consistent with Mortensen/Pissarides (1999, 2001) the hiring subsidy increases the equilibrium rate of unemployment $U$.

For example in the regime $\iota = 0$, where only PES placements are subsidised, $U$ increases from 7.4% ($H = 0$) to 8.4% ($H = 30$). In comparison: in the year 2000 the rate of unemployment in the OECD was in total 6.4% and in the EU 8.3%.

In the standard model of Mortensen/Pissarides the hiring subsidy lowers the costs of job creation, so that on the one hand job creation is stimulated and the duration of unemployment falls. On the other hand the unemployment incidence increases. Because of the increasing tightness the opportunity costs of a filled job rise and the match partners separate faster. The second effect outweighs the first so that overall employment decreases.

In our model three factors have an affect on equilibrium unemployment. First the incidence, second the duration of the unemployment spell and third the fraction of passive job seekers. If the fraction of passive job seekers rises then, ceteris paribus, unemployment increases because the passive seekers are unemployed for at least one period longer than the active seekers: $d_p > 1 + d_s$.

---

7 The following comparative data are taken from the OECD (2001 a,b)
The main causes for the positive correlation between ALMP and the unemployment rate in our model are the following. First, firms and worker only enjoy the benefits of the hiring subsidy if they are matched by the PES (regime \( t = 0 \)). The hiring subsidy therefore increases the opportunity costs of a start-up in the first and second phase of the search process. The consequences are that the fractions of active job seekers, \( S_t / I_t \times 100 \) and \( S_u / u \times 100 \), fall or that the fractions of those STU and LTU who prefer to wait for a placement through the PES increase. Second, the hiring subsidy reduces duration but only the duration of the active job seekers, \( d_S \), while the average spell length \( d_P \) of an unemployed worker who decides on the passive search strategy increases. The reason for this is that the growing number of passive job seekers is concentrated in the third phase of the matching process. As a result the tightness between the registers of the PES decreases, the time \( 1 + 1 / P(\theta) \), which elapses until the first job offer of the PES is made rises and the probability of a successful match falls. It is not surprising that the duration of the unemployment spell of the active job seeker falls because, on the one hand, the supply of vacancies rises due to the hiring subsidy and, on the other hand, the number of active job seekers falls.

ALMP thus increases not only the job destruction rate but also the duration of the unemployment spell of passive job seekers as well as their fraction of all unemployed.

The development of the fraction of the LTU who are randomly searching depends on the design of the ALMP. In the regime \( t = 0 \), where only PES placements are subsidised, the fraction of active job seekers among the LTU decreases. As a result the fraction of passive job seekers rises in \( t = 0 \) not only among the STU but also among the LTU.

Result 2. Although the hiring subsidy raises the fraction of active job seekers among the LTU and their duration \( d_S \) falls, the symmetrical labour market policy \( t = 1 \) lowers overall employment. However the symmetrical ALMP leads to a crowding-out of active job seekers among the STU and reduces the job-to-job transitions even below the level reached in the regime \( t = 0 \). As in \( t = 0 \) \( d_P \) increases and because the second effect outweighs the first unemployment rises. Nevertheless, due to the growing number of active job seekers among the LTU, the equilibrium rate of unemployment does not increase as much as it does in the regime \( t = 0 \).

Result 3. (1) In addition the fraction of the LTU (in \( t = 0 \)) – in the model those are the LTU who are unemployed for longer than 3 months (1 quarter) – increases from 72.0 % \( (H = 0) \) to 73.6 % \( (H = 30) \). (2) The costs for PLMP increase from 2.7% \( (H = 0) \) to 3.1% \( (H = 30) \) of the net product, while the costs for ALMP \( (H = 30) \) reach the value of 0.3% of the net product.
In comparison: in the year 2000 the incidence of “long-term unemployed” (3 months and over) was 65.3 % of total unemployment in the OECD and 75.6 % in the EU. Moreover, in 1999 the average OECD member incurred costs for UI benefits of 1.0 % of the GDP as well as costs for “subsidies to regular employment in the private sector” of 0.1 % of the GDP.

**Result 4.** Without ALMP ($H = 0$) the LTU placed through the PES must accept on average a 5.6 % wage penalty compared to a STU worker when making a job-to-job transition. ALMP ($H = 30$) turn this penalty into an advantage of 3.5 % for the LTU under the regime $\eta = 0$.

In comparison: based on the first seven rounds of the British Household Panel Survey, Arulampalam (2001) estimates that, after an unemployment spell, a worker must accept a wage penalty of 5.7 % compared to making a job-to-job transition.

The App. IV und V show clearly that the results 1 – 4 are also stable with shocks, which affect central model parameters. In addition the graphs depict two further interesting effects.

**Result 5.** The more effective the matching service of the PES – measured by the total factor productivity $e_{f}$ of the PES matching function under the regime $\eta = 0$ – the higher equilibrium unemployment is.

The reasons are ($H = 0$): first the more effective job placement service of the PES raises the opportunity costs of the filled jobs and therefore the incidence: While a job with $e_{f} = 0.30$ has a mean life span of $1/\lambda G(R) * 100 = 36$ quarters or 9.0 years, the life span falls to 8.2 years for $e_{f} = 0.35$. Second, the fraction of active job seekers among the STU and thus the fraction of the STU making job-to-job transitions decreases with increasing $e_{f}$. Third, even though the higher productivity of the PES lowers the unemployment duration of both search strategies – for the passive strategy the duration falls from 5 to 4.8 quarters, for the active from 1 to 0.9 quarters – the first two negative effects outweigh the positive third effect. Why does the duration of the unemployment spells decrease? The fact that $d_{P}$ falls is obviously due to the higher productivity of the PES which has the effect that the time lapse between two job offers is reduced. The decrease of $d_{S}$ results from the reduction in the number of the active job seekers among the LTU. This improves the chances of the remaining active searchers who stick to their search strategy.

Of course the fraction of PES matches, and thus the success which the PES will claim, grows with the effectiveness of its placement service.

**Result 6.** The increase in the bargaining power of the workers as shown in App. V from $\beta = 0.50$ to $\beta = 0.55$ lowers the life expectancy of a job from 9.0 to 8.7 years and increases the duration of the unemployment spells – the du-

---

* This wage penalty increases to 14 % in the fourth year after the unemployment spell and then decreases again (Arulampalam 2001).
RATION RISES BY ABOUT 18 DAYS: $d_P$ INCREASES FROM 5.0 TO 5.2 QUARTERS AND $d_S$ FROM 1 TO 1.2 QUARTERS. ALTHOUGH THE LIFE EXPECTANCY OF A JOB FALLS AND THE DURATION OF AN UNEMPLOYMENT SPELL RISES, OVERALL EMPLOYMENT INCREASES.

8. SUMMARY

match rent appropriated by the workers increases, while the profit share decreases. As a consequence the job destruction rate increases and the supply of vacancies is reduced. Second, a lower supply of vacancies reduces the transition rates into employment and durations grow. Third, the fact that unemployment does not increase but decreases is a consequence of the growing rate of active job seekers and of the fact that active in comparison with passive job seekers have a much shorter unemployment duration. The reason that the unemployed switch to the active search strategy and that the rate of passive job seekers falls is, naturally, the higher share of the match rent and the higher wages.

Of course, the PES can increase its placement success by improving the effectiveness of its matching service. Nevertheless, the job destruction rate will increase and the fraction of active job seekers among the STU will decrease so that the improved effectiveness of the PES will lead to an increase in equilibrium unemployment, although the unemployment duration for both groups of jobseekers, the passive and the active, is reduced.

The economic policy consequences of the model are clear: the effects of ALMP and profiling techniques to increase the effectiveness of the state placement service depend on the target group they are geared towards. First, for skill groups, who have relatively low private search costs in comparison with their productivity, not only the policy instruments of ALMP but also the actual job placement activities of the PES are counterproductive and reduce overall employment. Second, the instruments of ALMP and the placement service of the PES only have a stimulating effect in job creation for target groups with such high private search costs that in equilibrium without policy it is not worthwhile for these groups to actively search for a job.

APPENDIX I

Option values $V_p$ and $V_s$. 1. When firms decide whether to offer a vacancy they only know the c.d.f. of the training costs $F(t)$, the reservation costs $T_i$ and the conditions for PES subsidies $\tau \in \{i, r\}$. Before the training costs are revealed the asset value of a vacancy expecting a contact with a LTU worker placed by the PES is

$$V_p = \int_0^H \Pi_P(t) dF(t) + \int_H^{T_P} \Pi_P(t) + H - t dF(t). \quad (A1)$$

If the training costs of the LTU are fully subsidised, the job has the value $\Pi_P$. The second term in (A1) denotes the expected value of the job if the training costs are higher than the subsidy limit $H$ but below the reservation costs $T_P$. Finally, if the training costs exceed $T_P$, the match partners separate immediately. Analogously, before training costs are known the conditional option value of a vacancy that meets an active job seeker among the LTU is

$$V_s = \int_0^H \Pi_s(t) dF(t) + \int_H^{T_s} \Pi_s(t) + H - t dF(t) + \int_{T_s}^\infty QV_P dF(t). \quad (A2)$$

If the match specific training costs of the job seeker exceed $T_s$, the agents separate and, in view of the third round of the matching process, the vacancy takes on the value of the outside option $QV_P$.

2. With respect to the asset equations (32) – (35) and Lemma 3 the option values (A1) and (A2) of a vacancy transform to

$$V_p(T_P, H) = (1 - \beta) \left[ F(H)(T_P - H) + \int_H^{T_P} (T_P - t) dF(t) \right] \quad (A3)$$

$$V_s(\theta, T_P, T_s, H, r) = (1 - \beta) \left[ F(H)(T_s - H) + \int_{T_s}^{T_P} (T_s - t) dF(t) \right] + Q(\theta) V_p(T_P, H) \quad (A4)$$
APPENDIX II

The model equations in implicit form are:

\[ J^1(\Pi(t), \Pi_p, \Theta, \theta_i, \theta_S, R, T_p, T_S; H) = \Pi(t) - (1 - \beta) y \frac{1 - R}{\lambda + r} = 0 \]  \hspace{1cm} (A5)

\[ J^2() = \Pi(t) - \rho(1 - \beta) (1 - z)y - \Pi_p - \frac{\beta P(1 - q_i)(1 - q_S)}{1 - P(1 - q_j)(1 - q_S)} V_p(T_p, H) = 0 \]  \hspace{1cm} (A6)

\[ J^3() = \Pi_p - (1 - \beta)(T_p - H) = 0 \]  \hspace{1cm} (A7)

\[ J^4() = k - \frac{V_i(\Theta, T_p, T_S, \Theta_S, H, t)}{q_i(\theta_i)} - [\Pi(t) - (1 - \beta) V_i(\Theta, T_p, T_S, \Theta_S, H, t)] = 0 \]  \hspace{1cm} (A8)

\[ J^5() = R - \frac{b}{y} \frac{\Pi(t) - \rho(1 - \beta) (1 - z)y - \Pi_p}{(1 - \beta)y} + \frac{\lambda}{\lambda + r} \int \limits_{R}^{1} (h - R) dG(h) = 0 \]  \hspace{1cm} (A9)

\[ J^6() = T_p - T_S - (1 - i) H - Q(\Theta)V_p(T_p, H) = 0 \]  \hspace{1cm} (A10)

\[ J^7() = \frac{c_i}{P(\theta_i)} - \frac{\beta}{1 - \beta} [\Pi(t) - (1 - \beta) V_i(\Theta, T_p, T_S, \Theta_S, H, t)] = 0 \]  \hspace{1cm} (A11)

\[ J^8() = \frac{c_S}{(1 - q_j) P(\theta_S)} - \frac{\beta}{1 - \beta} [V_S(\Theta, T_p, T_S, H, t) - Q(\Theta)V_p(T_p, H)] = 0. \] \hspace{1cm} (A12)

The indicators PES and ALMP are defined as follows:

\[ PES = \frac{P(1 - q_i)(1 - q_S) F(T_p) (u - \rho S)}{u_S} \times 100 \] \hspace{1cm} (A13)

\[ ALMP = \frac{ALP + ALS}{np} \], where

\[ ALP = P(1 - q_i)(1 - q_S) F(T_p) (u - \rho S) \left[ \int \limits_{0}^{T_p} t F(t) + \int \limits_{T_S}^{T_p} H F(t) \right] / F(T_p) \]

\[ ALS = [u_S - P(1 - q_i)(1 - q_S) F(T_p) (u - \rho S) \left[ \int \limits_{0}^{T_S} t F(t) + \int \limits_{T_S}^{T_p} H F(t) \right] / F(T_S) \].
